

Appendix 6. Table Summarizing Survival Regression Models

Table 6.1. Survival regression models for selected constituents measured for in water samples collected at wells in the U.S. Geological Survey (USGS) aquifer water-quality monitoring network, Idaho National Laboratory and vicinity, Idaho. Detected values of constituent concentrations are represented as ‘interval-censored’ data by accounting for sampling variability.

[**Period of record:** is the most recent period after January 1, 1989 where continuous time series data are available. A time series is defined as continuous if the time span between consecutive samples never exceeds 3 years. α and β : are coefficients in the regression model, expressed as $\hat{C}(t) = \exp(\alpha + \beta t)$, where $\hat{C}(t)$ is the estimated constituent concentration at time t in days since January 1, 1970. The constituent concentration is in units of ‘milligrams per liter’ for 1,1,1-trichloroethane, chloride, chloroform, sodium, and sulfate; ‘milligrams per liter as nitrogen’ for nitrate; ‘micrograms per liter’ for chromium, carbon tetrachloride, and trichloroethylene; and ‘picocuries per liter’ for tritium and strontium-90. **Pseudo R^2 :** is the pseudo- R^2 computed using the McKelvey and Zavoina (1975) method. **p-value:** indicates the statistical significance of the regression. **Long-term trend:** is the percent increase in concentration per year estimated from the regression model. **Abbreviations:** <, less than; —, regression model could not be fit to measured data]
